

FlowRail.

One customer signature.
Forty payout keys that obey.

A signing desk for stablecoin payouts. Every payee gets their own key — with recipients, limits and expiry the chain itself enforces.

flowrail.vercel.app

github.com/Mofe-Bankole/Flowrail

MIT • open source

Tempo **Moderato** testnet

Forty payees. Two bad options.

Teams paying contractors in stablecoins today do one of two things. Both are wrong.

OPTION A

Approve one by one

Forty wallet confirmations every cycle. One wrong address, one wrong chain — someone's pay is gone. Ops becomes a click-farm.

OPTION B

Approve everything, once

One hot wallet, unlimited scope. A leaked key drains every payee at once — and the “rules” live in our backend, where they only guard a dashboard.

| Slow, or exposed. **There was no third option** — until the limits live on-chain.

One approval. The chain keeps score.

One signature releases this line. The other 39 need nothing from you.

Connect to sign

HELD, WITH A REASON

The one line that didn't release names its own rule — amount cap, per-token, per-payee. No silent failures.

TRY IT YOURSELF

Live at **flowrail.vercel.app/app** — desktop, no wallet needed to explore.

From one signature to forty enforced keys.

FAILURES INCLUDED

Published probes show exactly which calls the chain **refuses** — and why.

RECONCILABLE

A **memo on every transfer** (TIP-20 transferWithMemo) ties payouts to invoices.

TESTED

32 spike tests · typecheck + lint + build in one command: **npm run check**.

The policy isn't in our code. It's in the key.

TEMPO PRIMITIVE	TECHNICAL CAPABILITY	PRODUCT BEHAVIOUR	EXPERIENCE
<code>authorizeKey</code> 0x54063a55 · caps + expiry	Limits and lifetime stored per key, as chain state	The desk writes policy — not promises in a backend	Approve once. Exposure auto-expires.
<code>setAllowedCalls</code> 0xf5456703 · named recipients	A key can only pay the addresses it was given	Released funds can't be redirected or swept	Money goes only where you said.
Expiry, checked by the chain verified by probe: expired key → spend reverted	A late key is a dead key — no cooperation needed	Short-lived keys; owner can revoke mid-flight	No standing exposure.
<code>transferWithMemo</code> 0x95777d59 · TIP-20	Memo travels with the transfer itself	Invoices reconcile without our ledger	No spreadsheet archaeology.

Without Tempo there is only one key and one balance — spend rules collapse back into our backend, guarding a dashboard instead of the money. Built against the deployed ABI; spec gaps (TIP-1011) documented honestly in **docs/PROTOCOL.md**.

The dashboard can lie. The precompile can't.

CONVENTIONAL PAYOUT STACK

- 01 Rules enforced by our backend
- 02 One key, one balance — everything exposed
- 03 Demos hide the reverts
- 04 Built to the spec draft

FLOWRAIL ON TEMPO

- 01 Rules are key state on-chain
- 02 One key per payee: caps, recipients, expiry
- 03 Probes published — reverts included
- 04 Built to the deployed ABI; gaps documented

Escrow logic you must trust → spend permissions you can verify.

If payroll can be proven, finance can ship it.

WHO

Ops teams paying in stablecoins

- Finance leads paying **contractors & sellers** each cycle
- Any team choosing weekly between **40 clicks** and **one hot wallet**
- Builders on **Tempo** needing scoped spend, not escrow contracts

WHAT EXISTS NOW

Live, open source, testnet

- Working desk at **flowrail.vercel.app/app** — no wallet to explore
- **MIT** · github.com/Mofe-Bankole/Flowrail · 26 commits
- **spike** policy engine + probes, **web** desk — 32 tests passing

WHAT'S NEXT

Before real money moves

- **HSM-held root key** — replace file-based custody
- **Auth, nonce, rate limits** on the service layer
- **External audit**, then mainnet — order documented in THREAT-MODEL.md

Honest by construction: no real funds have moved — the failure modes are published, not patched over.

One signature.

Keys that obey the chain, not our code.
